

Race Condition

- **Unintended race condition** of 2 processes, which want to modify the value of the same record
 - The result of a process depends on the order or timing of other events
 - Frequent reason for bugs, which are hard to locate and fix
- Problem: The occurrence of the symptoms depends on different events
 - The symptoms may be different or disappear with each test run
- Race conditions can be avoided with the **semaphore** concept (⇒ slide 65)

Therac-25: Race Condition with tragic Result (1/2)

- Therac-25 is a linear particle accelerator for the radiation therapy of cancer tumors
- Mid-1980s: In the United States some accidents happened because of poor programming and quality assurance
 - Some patients got an up to 100 times increased radiation dose

An Investigation of the Therac-25 Accidents. Nancy Leveson, Clark S. Turner. IEEE Computer, Vol. 26, No. 7, July 1993, S.18-41
http://courses.cs.vt.edu/~cs3604/lib/Therac_25/Therac_1.html

Therac-25: Race Condition with tragic Result (2/2)

- A race condition („Texas-Bug“) led to incorrect settings of the device and consequently to increased radiation doses.
 - The control process did not synchronize correctly with the user interface process
 - The error occurred only during a quick input correction (time window: 8 seconds) by the user
 - During testing the error did not occur because experience (routine) was required to operate the device this fast

The Worst Computer Bugs in History: Race conditions in Therac-25:

<https://www.bugsnag.com/blog/bug-day-race-condition-therac-25>

„Once the data entry phase was marked complete, the magnet setting phase began. However, if a specific sequence of edits was applied in the Data Entry phase during the 8 second magnet setting phase, the setting was not applied to the machine hardware, due to the value of the completion variable. The UI would then display the wrong mode to the user, who would confirm the potentially lethal treatment.“

Forms of Interaction

- Communication and cooperation base on synchronization
 - Synchronization is the most elementary form of interaction
 - Reason: communication and cooperation need a synchronization between the interacting partners to obtain correct results
 - Therefore, we first discuss the **synchronization**

Most Simple Form of Signaling (Busy Waiting)

- The figure shows **busy waiting** at the signal variable `s`
 - The signal variable can be located in a local file, for example
 - Drawback: CPU resources are wasted, because the `wait` operation occupies the processor at regular intervals
- This technique is also called **spinlock** or **polling**

-
- The diagram illustrates the implementation of a semaphore using two mutexes, X and Y , and a counter variable s .
- Process 1 and Process 2:** Both processes have a critical section protected by a local mutex ($lock(s)$ and $unlock(s)$). Process 1's critical section is shaded light blue and labeled X . Process 2's critical section is shaded light blue and labeled Y . Arrows show that both processes can access both $lock(s)$ and $unlock(s)$ operations of the other process.
- Semaphore Operations:**
- unlock(s):** This operation is implemented by first acquiring mutex Y (via $lock(s)$), then decrementing the counter s (labeled "reset s"), and finally releasing mutex Y (via $unlock(s)$). A loop labeled "process waiting?" checks if $s > 0$. If "yes", it proceeds to "deblock process". If "no", it loops back to "process waiting?".
 - lock(s):** This operation is implemented by first checking if $s > 0$ ("is s set?"). If "yes", it proceeds to "set s" and then acquires mutex X (via $lock(s)$). If "no", it proceeds to "block process", which loops back to "is s set?".

Process 1

sigsuspend, kill, pause and sleep

- Alternative 1: Implementation of locking with the signals SIGSTOP (No. 19) and SIGCONT (No. 18)
 - With SIGSTOP another process can be stopped
 - With SIGCONT another process can be reactivated

- The relations of processes and resources can be visualized using directed graphs
- In this way, deadlocks can also be modeled
 - The nodes of a resource graph are:
 - **Processes:** Are shown as circles
 - **Resources:** Are shown as rectangles
 - An edge from a process to a resource means:
 - The process is blocked because it waits for the resource
 - An edge from a resource to a process means:
 - The process occupies the resource

A good description of resource graphs provides the book **Betriebssysteme – Eine Einführung**, Uwe Baumgarten, Hans-Jürgen Siegart, 6th Edition, Oldenbourg Verlag (2007), Chapter 6

Deadlock Detection with Matrices – Example (2/2)

- If process 3 finished execution, it deallocates its resources

Available resource vector = $\begin{pmatrix} 2 & 2 & 2 & 0 \end{pmatrix}$

$$\text{Request matrix} = \begin{bmatrix} 2 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 \\ - & - & - & - \end{bmatrix}$$

- 2 resources of class 1 are available
- 2 resources of class 2 are available
- 2 resources of class 3 are available
- No resources of class 4 are available
- If process 2 finished execution, it deallocates its resources

- Process 1 is blocked, because no free resources of class 4 exist
- **Process 2 is not blocked**

Available resource vector = $\begin{pmatrix} 4 & 2 & 2 & 1 \end{pmatrix}$

$$\text{Request matrix} = \begin{bmatrix} 2 & 0 & 0 & 1 \\ - & - & - & - \\ - & - & - & - \end{bmatrix}$$

- **Process 1 is not blocked** \Rightarrow no deadlock in this example

Communication of Processes

- Communication

- Shared Memory
- Message Queues
- Pipes
- Sockets

- Interprocess communication via a shared memory is also called **memory-based communication**
- **Shared memory segments** are memory areas, which can be accessed by multiple processes
 - These memory areas are located in the address space of multiple processes
- The processes need to coordinate the access operations by themselves and ensure that their memory requests are mutually exclusive
 - A receiver process, cannot read data from the shared memory, before the sender process has finished its current write operation
 - If access operations are not coordinated carefully \implies inconsistencies

exclusive usable memory

Working with Shared Memory

Linux/UNIX operating systems provide 4 system calls for working with shared memory

- `shmget()`: Create a shared memory segment or access an existing one
- `shmat()`: Attach a shared memory segment to a process
- `shmdt()`: Detach a shared memory segment from a process
- `shmctl()`: Request status information (e.g. privileges) of a shared memory segment, modify or erase it

One example of working with shared memory segments in Linux can be found on the website of this course

ipcs

The command `ipcs` provides information about existing shared memory segments

```
1 #include <sys/ipc.h>
2 #include <sys/shm.h>
3 #include <stdio.h>
4 #define MAXMEMSIZE 20
5
6 int main(int argc, char **argv) {
7     int shared_memory_id = 12345;
8     int returncode_shmget;
9
10    // Create shared memory segment or access an existing one
11    // IPC_CREAT = create a shared memory segment, if it does not still exist
12    // 0600 = Access privileges for the new message queue
13    returncode_shmget = shmget(shared_memory_id, MAXMEMSIZE, IPC_CREAT | 0600);
14
15    if (returncode_shmget < 0) {
16        printf("Unable to create the shared memory segment.\n");
17        perror("shmget");
18    } else {
19        printf("The shared memory segment has been created.\n");
20    }
21 }
```

28/75

Attach a Shared Memory Segment (in C)

```

1 #include <sys/types.h>
2 #include <sys/ipc.h>
3 #include <sys/shm.h>
4 #include <stdio.h>
5 #define MAXMEMSIZE 20
6
7 int main(int argc, char **argv) {
8     int shared_memory_id = 12345;
9     int returncode_shmget;
10    char *sharedmempointer;
11
12    // Create shared memory segment or access an existing one
13    returncode_shmget = shmget(shared_memory_id, MAXMEMSIZE, IPC_CREAT | 0600);
14    ...
15
16    // Attach shared memory segment
17    sharedmempointer = shmat(returncode_shmget, 0, 0);
18    if (sharedmempointer==(char *)-1) {
19        printf("Unable to attach the shared memory segment.\n");
20        perror("shmat");
21    } else {
22        printf("The shared memory segment has been attached %p\n", sharedmempointer);
23    }
24 }
25 }

```

```
$ ipcs -m
```

```

Prof. Dr. Christian Baun – 9th Slide Set Operating Systems – Frankfurt University of Applied Sciences – WS2021 30/75

Detach a Shared Memory Segment (in C)

```

1 #include <sys/types.h>
2 #include <sys/ipc.h>
3 #include <sys/shm.h>
4 #include <stdio.h>
5 #define MAXMEMSIZE 20
6
7 int main(int argc, char **argv) {
8     int shared_memory_id = 12345;
9     int returncode_shmget;
10    int returncode_shmdt;
11    char *sharedmempointer;
12
13    // Create shared memory segment or access an existing one
14    returncode_shmget = shmget(shared_memory_id, MAXMEMSIZE, IPC_CREAT | 0600);
15    ...
16
17    // Attach the shared memory segment
18    sharedmempointer = shmat(returncode_shmget, 0, 0);
19    ...
20
21    // Detach the shared memory segment
22    returncode_shmdt = shmdt(sharedmempointer);
23    if (returncode_shmdt < 0) {
24        printf("Unable to detach the shared memory segment.\n");
25        perror("shmdt");
26    } else {
27        printf("The shared memory segment has been detached.\n");
28    }
29 }
30 }

```

Erase a Shared Memory Segment (in C)

```

1 #include <sys/types.h>
2 #include <sys/ipc.h>
3 #include <sys/shm.h>
4 #include <stdio.h>
5 #define MAXMEMSIZE 20
6
7 int main(int argc, char **argv) {
8     int shared_memory_id = 12345;
9     int returncode_shmget;
10    int returncode_shmctl;
11    char *sharedmempointer;
12
13    // Create shared memory segment or access an existing one
14    returncode_shmget = shmget(shared_memory_id, MAXMEMSIZE, IPC_CREAT | 0600);
15    ...
16
17    // Erase shared memory segment
18    returncode_shmctl = shmctl(returncode_shmget, IPC_RMID, 0);
19    if (returncode_shmctl == -1) {
20        printf("Unable to erase the shared memory segment.\n");
21        perror("semctl");
22    } else {
23        printf("The shared memory segment has been erased.\n");
24    }
25 }
26 }

```

- Are linked lists with messages
- Operate according to the FIFO principle
- Processes can store data inside and pick them up from there
- Benefit: Even after the termination of the process, which created the message queue, the data inside the message queue stays available

- The command `ipcs` provides information about existing message queues

```

1 #include <stdlib.h>
2 #include <sys/types.h>
3 #include <sys/ipc.h>
4 #include <stdio.h>
5 #include <sys/msg.h>
6
7 int main(int argc, char **argv) {
8     int returncode_msgget;
9
10    // Create message queue or access an existing one
11    // IPC_CREAT => create a message queue, if it does not still exist
12    // 0600 = Access privileges for the new message queue
13    returncode_msgget = msgget(12345, IPC_CREAT | 0600);
14    if(returncode_msgget < 0) {
15        printf("Unable to create the message queue.\n");
16        exit(1);
17    } else {
18        printf("The message queue 12345 with the ID %i has been created.\n",
19              returncode_msgget);
20    }
21 }

```

34/75

```

1 #include <stdlib.h>
2 #include <sys/types.h>
3 #include <sys/ipc.h>
4 #include <stdio.h>
5 #include <sys/msg.h>
6 #include <string.h>           // This header file is required for strcpy()
7
8 struct msgbuf {               // Template of a buffer for msgsnd and msgrcv
9     long mtype;               // Message type
10    char mtext[80];           // Send buffer
11 } msg;
12
13 int main(int argc, char **argv) {
14     int returncode_msgget;
15
16     // Create message queue or access an existing one
17     returncode_msgget = msgget(12345, IPC_CREAT | 0600);
18     ...
19
20     msg.mtype = 1;            // Specify the message type
21     strcpy(msg.mtext, "Testnachricht"); // Write the message into the send buffer
22
23     // Write a message into the message queue
24     if (msgsnd(returncode_msgget, &msg, strlen(msg.mtext), 0) == -1) {
25         printf("Unable to write the message into the message queue.\n");
26         exit(1);
27     }
28 }

```

26         perror("msgrcv");
27     } else {
28         printf("This message was picked from the message queue: %s\n", msg.mtext);
29         printf("The received message is %i characters long.\n", returncode_msgrcv);
30     }
31 }

```

Erase a Message Queue (in C)

```
1 #include <stdlib.h>
2 #include <sys/types.h>
3 #include <sys/ipc.h>
4 #include <stdio.h>
5 #include <sys/msg.h>
6
7 int main(int argc, char **argv) {
8     int returncode_msgget;
9     int returncode_msgctl;
10
11     // Create message queue or access an existing one
12     returncode_msgget = msgget(12345, IPC_CREAT | 0600);
13     ...
14
15     // Erase message queue
16     returncode_msgctl = msgctl(returncode_msgget, IPC_RMID, 0);
17     if (returncode_msgctl < 0) {
18         printf("Unable to erase the message queue with the ID %i.\n", returncode_msgget);
19         perror("msgctl");
20         exit(1);
21     } else {
22         printf("The message queue with the ID %i has been erased.\n", returncode_msgget);
23     }
24     exit(0);
25 }
```

One example of working with message queues in Linux can be found on the website of this course

- An **anonymous Pipe**...

-
- The diagram illustrates a pipe as a communication channel between two processes. On the left, a box labeled "Process X" is identified as the "writing process". An arrow points from this box to a central pipe icon, which is a horizontal cylinder with a circular end on the right. The pipe is labeled "Pipe" and "contains the byte stream". Another arrow points from the right end of the pipe to a box on the right labeled "Process Y", which is identified as the "reading process". Both arrows are labeled with the string "abc..." to represent the data being transferred.

An Anonymous Pipe Example (in C) – Part 1/2

One example of working with named pipes in Linux can be found on the website of this course

```
1 #include <stdio.h>
2 #include <unistd.h>
3 #include <stdlib.h>
4
5 void main() {
6     int pid_des_Kindes;
7     // Zugriffskennungen zum Lesen (testpipe[0]) und Schreiben (testpipe[1]) anlegen
8     int testpipe[2];
9
10    // Die Pipe testpipe anlegen
11    if (pipe(testpipe) < 0) {
12        printf("Das Anlegen der Pipe ist fehlgeschlagen.\n");
13        // Programmabbruch
14        exit(1);
15    } else {
16        printf("Die Pipe testpipe wurde angelegt.\n");
17    }
18
19    // Einen Kindprozess erzeugen
20    pid_des_Kindes = fork();
21
22    // Es kam beim fork zu einem Fehler
23    if (pid_des_Kindes < 0) {
24        perror("Es kam bei fork zu einem Fehler!\n");
25        // Programmabbruch
26        exit(1);
27    }
```

An Anonymous Pipe Example (in C) – Part 2/2

```

28 // Elternprozess
29 if (pid_des_Kindes > 0) {
30     printf("Elternprozess: PID: %i\n", getpid());
31     // Lese kanal der Pipe testpipe blockieren
32     close(testpipe[0]);
33     char nachricht[] = "Testnachricht";
34     // Daten in den Schreibkanal der Pipe schreiben
35     write(testpipe[1], &nachricht, sizeof(nachricht));
36 }
37
38 // Kindprozess
39 if (pid_des_Kindes == 0) {
40     printf("Kindprozess: PID: %i\n", getpid());
41     // Schreibkanal der Pipe testpipe blockieren
42     close(testpipe[1]);
43     // Einen Empfangspuffer mit 80 Zeichen Kapazität anlegen
44     char puffer[80];
45     // Daten aus dem Lese kanal der Pipe auslesen
46     read(testpipe[0], puffer, sizeof(puffer));
47     // Empfangene Daten ausgeben
48     printf("Empfangene Daten: %s\n", puffer);
49 }
50 }

```

```
$ gcc pipe_beispiel.c -o pipe_beispiel
```

```
$ ./pipe_beispiel
```

```
Die Pipe testpipe wurde angelegt.
```

```
Elternprozess: PID: 6363
```

```
Kindprozess: PID: 6364
```

```
Empfangene Daten: Testnachricht
```

Sockets

- Full duplex-ready alternative to pipes and shared memory
 - Allow interprocess communication in distributed systems
- An user process can request a socket from the operating system and afterwards send and receive data via the socket
 - The operating system maintains all used sockets and the related connection information

- Ports are used for the communication via sockets
 - Port numbers are randomly assigned during connection establishment
 - Port numbers are assigned randomly by the operating system
 - Exceptions are port numbers of well-known applications, such as HTTP (80) SMTP (25), Telnet (23), SSH (22), FTP (21),...
- Sockets can be used in a blocking (synchronous) and non-blocking (asynchronous) way

Different Types of Sockets

- **Connectionless sockets (= datagram sockets)**
 - Use the Transport Layer protocol UDP
 - Advantage: Better data rate as with TCP
 - Reason: Lesser overhead for the protocol
 - Drawback: Segments may arrive in wrong sequence or may get lost
- **Connection-oriented sockets (= stream sockets)**
 - Use the Transport Layer protocol TCP
 - Advantage: Better reliability
 - Segments cannot get lost
 - Segments always arrive in the correct sequence
 - Drawback: Lower data rate as with UDP
 - Reason: More overhead for the protocol

Using Sockets

- Almost all major operating systems support sockets
 - Advantage: Better portability of applications
- Functions for communication via sockets:
 - Creating a Socket:
`socket()`
 - Binding a socket to a port number and making it ready to receive data:
`bind()`, `listen()`, `accept()` and `connect()`
 - Sending/receiving messages via the socket:
`send()`, `sendto()`, `recv()` and `recvfrom()`
 - Closing eines Socket:
`shutdown()` or `close()`

Overview of the sockets in Linux/UNIX: `netstat -n` or `lsof | grep socket`

Connection-less Communication via Sockets – UDP

• Client

- Create socket (`socket`)
- Send (`sendto`) and receive data (`recvfrom`)
- Close socket (`close`)

• Server

- Create socket (`socket`)
- Bind socket to a port (`bind`)
- Send (`sendto`) and receive data (`recvfrom`)
- Close socket (`close`)

Connection-oriented Communication via Sockets – TCP

• Client

- Create socket (`socket`)
- Connect client with server socket (`connect`)
- Send (`send`) and receive data (`recv`)
- Close socket (`close`)

• Server

- Create socket (`socket`)
- Bind socket to a port (`bind`)
- Make socket ready to receive (`listen`)
 - Set up a queue for connections with clients
- Server accepts connections (`accept`)
- Send (`send`) and receive data (`recv`)
- Close socket (`close`)

Create a Socket: socket

```
int socket(int domain, int type, int protocol);
```

- A call of `socket()` returns an integer value
 - The value is called **socket descriptor** (*socket file descriptor*)
- `domain`: Specifies the protocol family
 - `PF_UNIX`: Local interprocess communication in Linux/UNIX
 - `PF_INET`: IPv4
 - `PF_INET6`: IPv6
- `type`: Specifies the type of the socket (and thus the protocol):
 - `SOCK_STREAM`: Stream socket (TCP)
 - `SOCK_DGRAM`: Datagram socket (UDP)
 - `SOCK_RAW`: RAW socket (IP)
- In most cases the `protocol` parameter is set to value zero
- Create a socket with `socket()`:

```
1 sd = socket(PF_INET, SOCK_STREAM, 0);  
2     if (sd < 0) {  
3         perror("The socket could not be created");  
4         return 1;  
5     }
```

Bind Address and Port Number: bind

```
int bind(int sd, struct sockaddr *address, int addrlen);
```

- `bind()` binds the newly created socket (`sd`) to the address (`address`) of the server
 - `sd` is the socket descriptor from the previous call of `socket()`
 - `address` is a data structure, which contains the IP address of the server and a port number
 - `addrlen` is the length of the data structure, which contains the IP address and port number

Make a Server ready to receive Data: listen

```
int listen(int sd, int backlog);
```

- `listen()` specifies how many connection requests can be buffered by the socket
 - If the `listen()` queue has no more free capacity, further connection requests from clients are rejected
 - `sd` is the socket descriptor from the previous call of `socket()`
 - `backlog` contains the number of possible connection requests, which can be stored in the queue
 - Default value: 5
 - A server for datagrams (UDP) does not need to call `listen()`, because it does not establish connections to clients

Establish a Connection by the Client

```
int connect(int sd, struct sockaddr *servaddr,
            socklen_t addrlen);
```

- Via `connect()`, the client tries to establish a connection to a server socket
- The client must know the address (hostname and port number) of the server
- `sd` is the socket descriptor
- `address` contains the address of the server
- `addrlen` is the length of the data structure, which contains the address of the server

Connection-oriented Exchange of Data: send and recv

```
int send(int sd, char *buffer, int nbytes, int flags);  
int recv(int sd, char *buffer, int nbytes, int flags);
```

- Data are exchanged via `send()` and `recv()` over an existing connection
- `send()` sends a message (`buffer`) via the socket (`sd`)
- `recv()` receives a message from the socket `sd` and stores it in the buffer (`buffer`)
- `sd` is the socket descriptor
- `buffer` contains the data to be sent or received
- `nbytes` specifies the number of bytes in the buffer
- The value of `flags` is usually zero

Connection-oriented Exchange of Data: read and write

```
int read(int sd, char *buffer, int nbytes);  
int write(int sd, char *buffer, int nbytes);
```

- In UNIX it is in normal case also possible to use `read()` and `write()` for receiving and sending data via a socket
 - „Normal case“ means, that `read()` and `write()` can be used, when the parameter flags of `send()` and `recv()` contains value zero
- The following calls have the same result

```
1 send(socket, "Hello World", 11, 0);  
2 write(socket, "Hello World", 11);
```

Connection-less Exchange of Data: `sendto` and `recvfrom`

```
int sendto(int sd, char *buffer, int nbytes, int flags,
           struct sockaddr *to, int addrlen);
int recvfrom(int sd, char *buffer, int nbytes, int flags,
             struct sockaddr *from, int addrlen);
```

- If a process knows the address of the socket (host and port), to which it should send data, it uses `sendto()`
- `sendto()` always transmits together with the data the local address
- `sd` is the socket descriptor
- `buffer` contains the data to be sent or received
- `nbytes` specifies the number of bytes in the buffer
- `to` contains the address of the receiver
- `from` contains the address of the sender
- `addrlen` is the length of the data structure, which contains the address

Close a Socket: close

```
int shutdown(int sd, int how);
```

- `shutdown()` closes a bidirectional socket connection
- The parameter `how` specifies whether no more data will be received (`how=0`), no more data will be send (`how=1`), or both (`how=2`)

```
int close(int sd);
```

- If `close()` is used instead of `shutdown()`, this corresponds to a `shutdown(sd,2)`

Sockets via UDP – Example (Server)

```

1  #!/usr/bin/env python
2  # Server: Receives a message via UDP
3
4  import socket                # Import module socket
5
6  # For all interfaces of the host
7  HOST = ''                    # '' = all interfaces
8  PORT = 50000                 # Port number of server
9
10 # Create socket and return socket descriptor
11 sd = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)
12
13 try:
14     sd.bind((HOST, PORT))     # Bind socket to port
15     while True:
16         # Receive data
17         data = sd.recvfrom(1024)
18         # Print received data
19         print 'Received:', repr(data)
20 finally:
21     sd.close()                # Close socket

```

```
$ python udp_server.py
```

Sockets via UDP – Example (Client)

```
1 #!/usr/bin/env python
2 # Client: Sends a message via UDP
3
4 import socket                # Import module socket
5
6 HOST = 'localhost'          # Hostname of Server
7 PORT = 50000                 # Port number of Server
8 MESSAGE = 'Hello World'     # Message
9
10 # Create socket and return socket deskriptor
11 sd = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)
12
13 # Send message to socket
14 sd.sendto(MESSAGE, (HOST, PORT))
15
16 sd.close()                   # Close socket
```

```
$ python udp_client.py
```

```
$ python udp_server.py
Received: ('Hello World', ('127.0.0.1', 39834))
```

Sockets via TCP – Example (Server)

```

1  #!/usr/bin/env python
2  # Echo Server via TCP
3  import socket                # Import module socket
4
5  HOST = ''                    # '' = all interfaces
6  PORT = 50007                 # Port number of server
7
8  # Create socket and return socket descriptor
9  sd = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
10 # Bind socket to port
11 sd.bind((HOST, PORT))
12 # Make socket ready to receive
13 # Max. number of connections = 1
14 sd.listen(1)
15 # Socket accepts connections
16 conn, addr = sd.accept()
17
18 print 'Connected by', addr
19
20 while 1:                     # Infinite loop
21     data = conn.recv(1024)    # Receive data
22     if not data: break        # Break infinite loop
23     conn.send(data)           # Send back received data
24
25 conn.close()                 # Close socket

```

```
$ python tcp_server.py
```

Sockets via TCP – Example (Client)

```

1  #!/usr/bin/env python
2  # Echo Client via TDP
3
4  import socket                # Import module socket
5
6  HOST = 'localhost'          # Hostname of Server
7  PORT = 50007                # Port number of server
8
9  # Create socket and return socket descriptor
10 sd = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
11 # Connect with server socket
12 sd.connect((HOST, PORT))
13
14 sd.send('Hello, world')      # Send data
15 data = sd.recv(1024)         # Receive data
16 sd.close()                   # Close socket
17
18 # Print received data
19 print 'Empfangen:', repr(data)

```

```

$ python tcp_client.py
Empfangen: 'Hello, world'

```

```

$ python tcp_server.py
Connected by ('127.0.0.1', 49898)

```

Blocking and non-blocking Sockets

- If a socket is created, it per default in **blocking mode**
 - All method calls wait until the operation, they initiated, was carried out
 - e.g. a call of `recv()` blocks the process until data is received and can be read from the internal buffer of the socket
- The method `setblocking()` **modifies** the mode of a socket
 - `sd.setblocking(0)` \implies switches into non-blocking mode
 - `sd.setblocking(1)` \implies switches into blocking mode
- It is possible to switch between the modes **at any time** during process execution
 - e.g. the method `connect()` could be used in blocking mode and afterwards the method `read()` in non-blocking mode

Semaphore

- In order to protect (lock) critical sections, not only the already discussed locks can be used, but also **semaphores**
- 1965: Published by Edsger W. Dijkstra
- A semaphore is a counter lock **S** with operations **P(S)** and **V(S)**
 - **V** comes from the dutch *verhogen* = raise
 - **P** comes from the dutch *proberen* = try (to reduce)
- The **access operations are atomic** \implies can not be interrupted (indivisible)
- May allow multiple processes accessing the critical section
 - In contrast to semaphores, can locks (\implies slide 14) only be used to allow a single process entering the critical section at the same time

Cooperating sequential processes. *Edsger W. Dijkstra* (1965)

<https://www.cs.utexas.edu/~EWD/ewd01xx/EWD123.PDF>

Image Source: Carsten Vogt

- ```
1 SEM.P() {
2 // if the counter variable = 0, the process becomes blocked
3 if (SEM.COUNT == 0)
4 < block >
5
6 // if the counter variable is > 0, the counter variable
7 // is decremented immediately by 1
8 SEM.COUNT = SEM.COUNT - 1;
9 }
```

Image Source: Carsten Vogt

- ```
SEM.V() {
    // counter variable = counter variable + 1
    SEM.COUNT = SEM.COUNT + 1;

    // if processes are in the waiting room, one gets deblocked
    if ( < SEM waiting room is not empty > )
        < deblock a waiting process >
}
```

-
- Diagram illustrating the structure of a semaphore table:
- The **Semaphore table** is indexed by **Group number** (0, 1, 2, 3, ..., n).
 - Each entry in the table points to a **Semaphore group**.
 - The **Semaphore group** contains individual semaphores, indexed by **Semaphore number within the group** (0, 1, 2, 3, 4, 5).
 - Examples of semaphore groups:
 - Group 0: $S_{00}, S_{01}, S_{02}, S_{03}, S_{04}, S_{05}$
 - Group 1: S_{10}, S_{11}
 - Group 2: S_{20}, S_{21}, S_{22}
 - Group 3: $S_{30}, S_{31}, S_{32}, S_{33}, S_{34}$
 - The entry for group n is labeled **empty**.

- `semget()`: Create new semaphore or a group of semaphores or open an existing semaphore
- `semctl()`: Request or modify the value of an existing semaphore or of a semaphore group or erase a semaphore
- `semop()`: Carry out P and V operations on semaphores
- Information about existing semaphores provides the command `ipcs`

Mutexes

- Semaphores offer the feature of counting
- However, if this feature is not required, a simplified semaphore version, the mutex can be used instead
 - **Mutexes** (derived from **Mutual Exclusion**) are used to protect critical sections, which are allowed to be accessed by only **a single process** at any given moment
 - Mutexes can only have 2 states: **occupied** and **not occupied**
 - Mutexes have the same functionality as **binary semaphores**

2 functions for accessing a Mutex exist

mutex_lock \Rightarrow corresponds to the P operation

`mutex_unlock` \Rightarrow corresponds to the V operation

- If a process wants to access a critical section, it calls `mutex_lock`
 - If the critical section is **locked**, the process gets locked, until the process in the critical section is finished and calls `mutex_unlock`
 - If the critical section is **not locked**, the process can enter it

Monitor and erase IPC Objects

- Information about existing shared memory segments provides the command `ipcs`
- The easiest way to erase semaphores, shared memory segments and message queues from the command line is the command `ipcrm`

```
ipcrm [-m shmids] [-q msgids] [-s semids]
      [-M shmkeys] [-Q msgkeys] [-S semkeys]
```

- Or alternatively just...
 - `ipcrm shm SharedMemoryID`
 - `ipcrm sem SemaphoreID`
 - `ipcrm msg MessageQueueID`
